

Typescript Assignment

1. Create fields variable which contains the sample data given below
2. Combined all the items from Details, Measures, Dimensions, Hierarchies into single variable named fieldList
3. Filter fieldList to get the array that contains “calculatedFieldKey” key in it and save that array in variable named calculatedfields
4. Find the index of the item whose entityName is “Discount” and remove that item from the fieldList
5. Change the flag isNumericDataType to true and datatype to Numerical whose entityName is “City”
6. Combine variables array into single array from the calculatedfields and find the variables list whose variableType is “numerical”
7. From Dimensions array from fields store the index of the item whose Parent" = "Order Date" into array named dataIndex.
8. Loop over Dimensions array and check if the index of the item is present in dataIndex array and if present then print the entityName of that item
9. From Measures array from the fields change the key “datasetId” to “datasetKey” or add new key “datasetKey” with same value as “datasetId”
10. Find the item from the fieldList with "variableType" = "geographical" and then make unMappedLocationCount = 5
11. Find items from the fields array whose isNumericDataType = true and datatype = float then change subDatasetId to datasetId and save all the items in array named NumericalItems
